Fungible Power Architectures for the 800V DC Transition

Vertically integrated from innovation to operation

The challenge with native 800VDC at the facility level

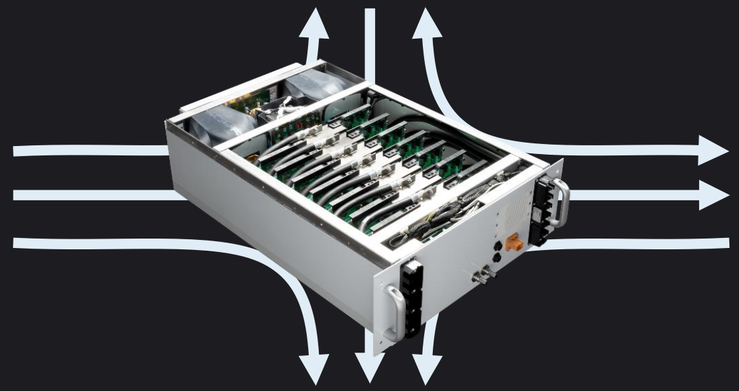

- Ignores the mechanical plant, compute, storage and network components still running on AC
- First of kind scaling risk for new 800VDC systems
- Duplication, white space inefficiency, power stranding, supply chain delays, overprovisioning
- Complex vendor landscape makes it almost impossible to chart 800V adoption curve

Innovate → Build → Deploy → Operate → Re-Innovate

- Problem set the same as the transition to liquid cooling
- Fixed-function system components force architecture decisions to design
- Fungible infrastructure solutions that enable late-binding
- From multi-temp chiller plants to multi-port SSTs

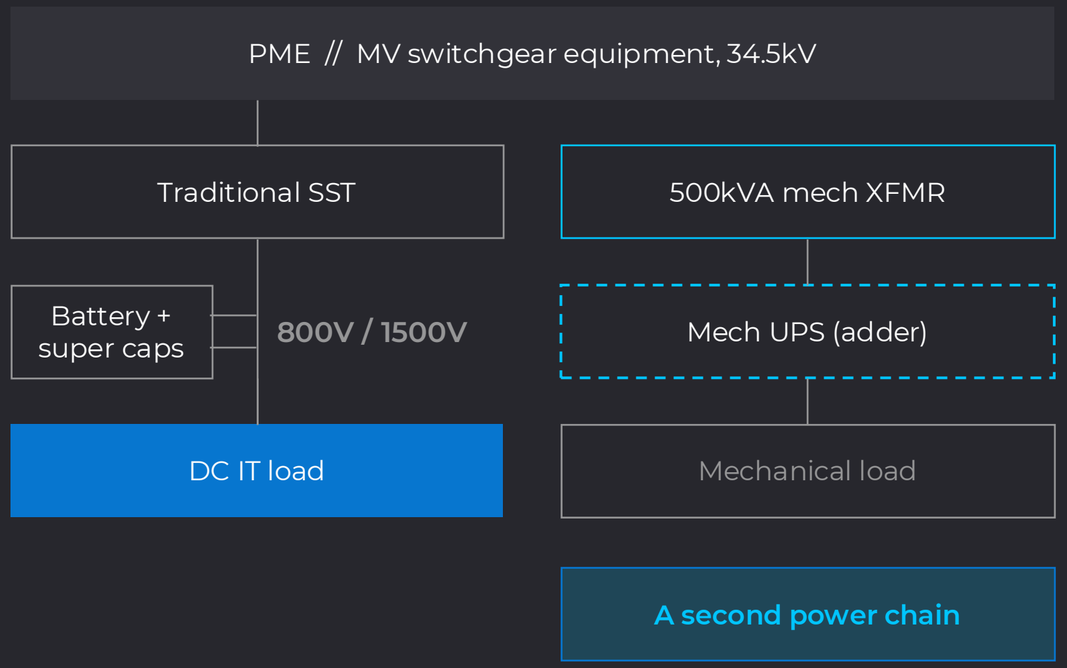

AC AND/OR DC

Two ways to build the same rack

Traditional SST build

Mechanical loads get their own transformer and UPS.

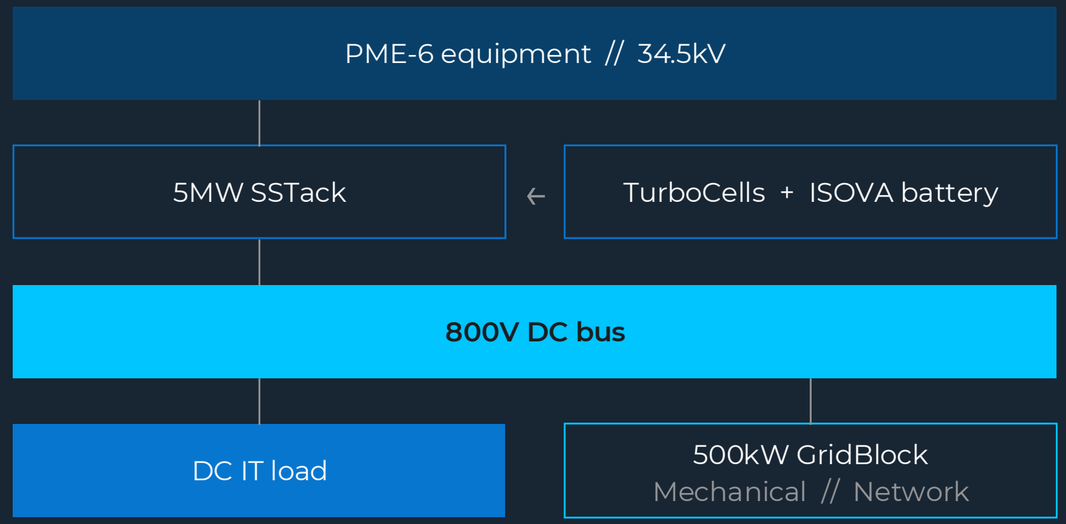

A second power chain.

With Power Router (GridBlock) on the bus

That second chain disappears.

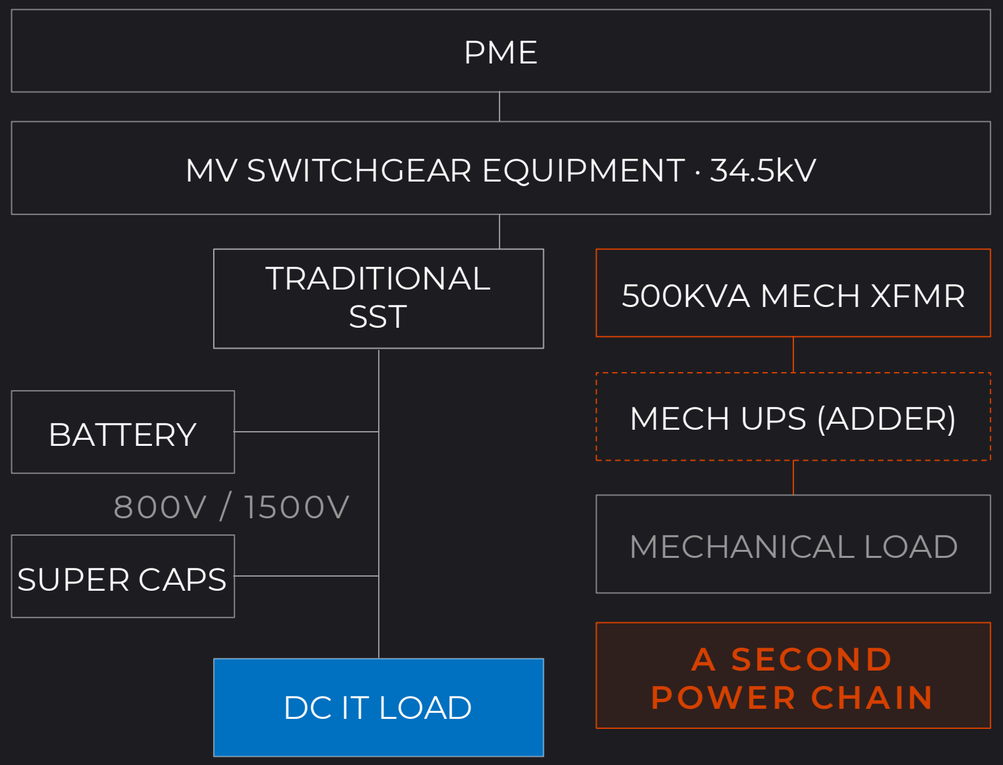

One 800V DC bus serves every load type.
